

Computer science
Higher level
Paper 2

Wednesday 18 November 2015 (morning)

1 hour 20 minutes

Instructions to candidates

- Do not open this examination paper until instructed to do so.
- Answer all of the questions from one of the options.
- The maximum mark for this examination paper is **[65 marks]**.

Option	Questions
Option A – Databases	1–4
Option B – Modelling and simulation	5–8
Option C – Web science	9–13
Option D – Object-oriented programming	14–19

Option A — Databases

1. After attending a database course, Paul, the owner of a small shop, decided to create and implement a customer database.

(a) (i) Identify **one** benefit of creating a database. [1]

(ii) Identify **one** cost of the implementation. [1]

Consider this section of his customer database file.

CustomerTable

Name	Date	ItemOrdered	QuantityOrdered	InvoiceAmount
Ann Low	18/04/2015	1713	4	200.00
Boris Nicke	18/04/2015	1324	3	180.00
Greta Pink	18/04/2015	1713	3	150.00
Rob Nool	19/04/2015	1648	7	360.00
Ann Low	19/04/2015	1713	5	250.00
Ivor Turk	20/04/2015	1423	6	105.00

(b) (i) State the number of fields that are in each record of the CustomerTable. [1]

(ii) Describe, using an example from the table above, why the customer’s name is **not** an appropriate primary key. [2]

(iii) Define the term *secondary key*. [1]

(c) Describe the steps in a query that will list all items for which more than five were ordered on 19/04/2015. [4]

Paul finds that the response time that will database queries is very slow.

(d) Explain what Paul could do to improve the response time without making changes to his hardware. [5]

(Option A continues on the following page)

(Option A continued)

2. A company lets tourists hire bikes. The data about bikes and hirers is stored in a database file. The following table shows this data for one day.

BikeHireTable

HirerID	HName	HPhone	TimeOut	TimeIn	BikeID	BikeMake	BikeModel
BL567	Boris Lok	99123456	09:00	11:00	DU12	BMS_11	A
CL167	Ivy Lok	93123455	09:00	11:00	DU14	AVG_00	B
AL751	Ann Summer	43453657	09:00	17:00	DU54	AVG_00	A
FC345	Fred Cohen	38321432	10:00	15:00	DU23	XYZ_94	C
...

The structure of the table can be summarized using the following **shorthand notation**.

BikeHireTable

(HirerID, HName, HPhone, TimeOut, TimeIn, BikeID, BikeMake, BikeModel)

- (a) Identify **three** functions of a database management system in an application such as hiring bikes. [3]

There are several aspects of the BikeHireTable that are unsatisfactory and it is decided to normalize this database.

- (b) Outline the purpose of normalization. [2]

- (c) State the characteristics of

(i) 1st Normal form (1NF); [1]

(ii) 2nd Normal form (2NF); [1]

(iii) 3rd Normal form (3NF). [1]

- (d) Construct the database to 3NF. Using the **shorthand notation**, clearly show the structure of the database in the **1st, 2nd and 3rd** normal forms. [7]

(Option A continues on the following page)

(Option A continued)

3. (a) Distinguish between the logical and the physical design of a database. [4]
- (b) Identify **three** items of information that a data dictionary contains. [3]
- (c) Explain **two** responsibilities of a database administrator. [4]

An online information service provides a database of job openings and also posts users' details. Users can view job listings and reply electronically with their details to the jobs that interest them.

- (d) Discuss **one** advantage and **one** disadvantage of using a database in this online information service. [4]
4. In a certain country an educational data warehouse team develops data reports. These data reports list every student's personal data, test scores, academic performance ratings and grades.

- (a) Define the term *data warehouse*. [2]
- (b) Explain the need for ETL processes in data warehousing. [4]

Different users of the data warehouse have different views and access rights.

- (c) Describe the advantages of using this educational data warehouse for
- (i) teachers; [2]
- (ii) school administrators. [2]
- (d) Outline **two** methods to ensure security of the data warehouse. [4]
- (e) (i) Compare classification and forecasting in the context of data mining. [3]
- (ii) Discuss how the use of predictive modelling could help to improve the educational system in the country. [3]

End of option A

Option B — Modelling and simulation

5. Air pollution is a concern for public health. One measure of air pollution is the amount of PM10 (particles measuring less than 10 micrometres) in the air. European legislation has been put into place which requires that any town with over 100 000 inhabitants has to keep within the following limits of PM10:

1. The average PM10 value in one day must not exceed 50 micrograms per cubic metre ($50 \mu\text{g m}^{-3}$) more than 35 times in the year.
2. The daily values averaged across the whole year (measured from 1 January) must not exceed 40 micrograms per cubic metre ($40 \mu\text{g m}^{-3}$).

In an industrial town, PM10 measurements are taken once an hour, recorded and stored. A complete model of hourly measurements is built up over the year. At the end of the year the town produces a report which includes the following:

- a chart of the average daily values
- the number of days the average exceeded $50 \mu\text{g m}^{-3}$
- the daily values averaged across the year.

(a) Outline, using a sketch or otherwise, a method of organizing the stored data in a spreadsheet for easy reference and analysis. [3]

Each day the average value from the previous day is published in the local press, together with the number of days, if any, that the daily limit ($50 \mu\text{g m}^{-3}$) has been exceeded since 1 January.

(b) Describe how the hourly results could be used to output the results required daily and also to produce an end-of-year report. [5]

The model can be used to produce data on patterns of pollution over time.

(c) (i) Identify **two** of these patterns. [2]

(ii) Explain how one of the patterns from part (c)(i) could help the town plan for the future. [2]

At one point in the year, the town’s daily values, averaged since 1 January, are $45 \mu\text{g m}^{-3}$. A “no car” weekend is introduced, in which people are not allowed to drive their cars within the town. It successfully reduces the average PM10 count but has a negative effect on local commerce.

(d) Explain how the model could be used to estimate the minimum number of “no car” weekends that would be needed to keep the town’s daily values averaged across the year from exceeding $40 \mu\text{g m}^{-3}$. [5]

(Option B continues on the following page)

(Option B continued)

6. A game for very young children is played on a board, which is represented by a 4×4 square. The game requires two players

The aim of the game is to be the first player to reach HOME which is the bottom right square. The players take turns to move between squares.

Players can move to an adjacent square which, from their current position, is:

- vertically down
- horizontally to the right
- diagonally in the direction of HOME.

If one of the moves is blocked by the other player, the player can jump over the other player and land in the square on the opposite side.

In the following diagram, player A is in square 1 and player B is in square 6.

A	2	3	4
5	B	7	8
9	10	11	12
13	14	15	HOME

(a) List the possible squares to which player A is able to move.

[1]

(Option B continues on the following page)

(Option B, question 6 continued)

(b) Player A moves to square 2 and then player B moves to square 10.

1	A	3	4
5	6	7	8
9	B	11	12
13	14	15	HOME

For each of the moves that player A **could now take**, suggest and justify the best move that player B **could then take**. [3]

The game is simulated by a computer program.

- (c) (i) Outline **one** way of representing player A and player B, and their positions, in memory. [2]
- (ii) Using your structure from part (c)(i), state the current positions of player A and player B, as shown in the diagram in part (b). [1]
- (iii) Using your answer to part (c)(i), outline how each **possible** move from the player's current position could be identified. [2]
- (iv) Suggest how a **best move** could be selected from the possible moves. [3]

The computer will always attempt to find the best path to the HOME square.

- (d) Outline the effect that changing to a much larger board would have on running the game on a computer. [4]

(Option B continues on the following page)

(Option B continued)

7. A self-driving car relies on a series of lasers and cameras that combine with high definition maps to give a three-dimensional (3D) view of the environment. Rules are programmed into the system so that the car drives at an optimum speed, keeps a safe distance from any vehicle in front, uses fuel economically and follows the traffic regulations.
- (a) Outline the need for high definition maps held in memory. [2]
 - (b) Outline how analysing successive 3D images in memory helps the car to drive safely. [3]
 - (c) Outline the time and memory needs of 3D visualization in this situation. [3]
 - (d) Discuss the social implications of self-driving cars. [4]
8. Consider the following quotation from Professor Heng Ji, an expert in natural language processing.
- “Computer searches currently have certain limitations. If you want to use Google, for example, you have to come up with intelligent keywords, you can only search in your own language and your search may return thousands of documents. A computer that could understand natural language could overcome those limitations, and our goal is to build that computer.”
- One task in which the author Heng Ji has been involved is the creation of a program for *New York Times* journalists to search social networks for breaking news.
- “As a first step in its process, the team manually labels a sampling of documents – for example, tweets of news events – to establish a set of ground rules for natural language. The computer uses a machine learning algorithm to apply the ground rules to additional documents it examines.”
- (a) Outline the aspects of natural language that make natural language processing difficult for a computer. [4]
 - (b) Outline the use of genetic algorithms in the above problem. [4]
 - (c) Compare **two** approaches to the development of machine learning. [4]
 - (d) Discuss the effect of using speech recognition in the above example. [3]
 - (e) Evaluate the advantages and disadvantages to society of the rapid and sophisticated analysis of information on social networks. [5]

End of option B

Option C — Web science

9. The code below is part of an XML (*Extensible Mark-up Language*) document that contains details of a DVD collection.

```
<collection>
  <dvd>
    <title>The Hobbit</title>
    <genre>Fantasy</genre>
  <dvd>
    <title>Sleepless in Seattle</title>
    <genre>Romance</genre>
  </dvd>
<!--more DVDs entered here-->
</collection>
```

(a) Identify the error in the section of XML code shown above. [1]

In some applications, XML is used instead of HTML principally because of its extensibility property.

(b) Outline the meaning of this property in the context of XML code. [2]

(c) Describe **one** benefit of storing HTML formatting information in a CSS file. [2]

An XML document contains details of a person’s DVD collection. The XML code will be sent to the web server using the internet protocol suite, which includes the TCP and IP protocols.

(d) Describe how these two protocols work together when sending data over the internet. [4]

The following web form is part of a login page for an online shopping site.

Name	<input type="text"/>
Email	<input type="text"/>
Country	<input type="text"/>

(e) (i) Explain how client-side scripting might be used on this login page before the page is sent to the web server of the shopping site. You should make reference to any software used. [3]

(ii) Outline the benefit of using client-side scripting for the shopping site. [2]

A social networking site stores multiple profile photographs of each client on its web server.

(f) Explain how the use of scripts allows the user to change their profile photograph without reloading the complete page. [4]

(Option C continues on the following page)

(Option C continued)

10. When a user requests a file from a particular website, the website uses lossy compression to send the file to the user over the internet.

(a) Discuss how this use of lossy compression might affect the user’s experience. [5]

The three essential processes of a web search engine are:

- crawling
- indexing
- searching.

(b) Outline the functions of each of these three processes. [6]

(c) Explain why the PageRank algorithm might discriminate against new websites. [3]

(d) Explain how a search engine is able to maintain an up-to-date index when the web is continually expanding. [3]

11. A large online retail company is relocating to a new purpose-built site and is considering incorporating cloud computing into its IT strategy.

(a) Describe **two** architectural features that are essential components of a sustainable public cloud computing model. [4]

In making decisions regarding their computing facilities, the company has to consider the following factors:

- the storage of sensitive financial data
- the extensive use of email for promotional purposes
- the increased demand over the Christmas period
- any upcoming development projects.

Many companies now use a hybrid approach to cloud computing in which they make use of both private and public clouds.

(b) Explain how this particular company might use a hybrid approach. [6]

(Option C continues on the following page)

(Option C continued)

- 12.** The development of the web has been largely unregulated.
- (a) Discuss how this lack of regulation has led to difficulties in extracting information from the web and how the use of ontologies would better facilitate the extraction of meaningful information. [5]
- The principles of collective intelligence are constantly used by organizations.
- (b) Define *collective intelligence* with respect to an organization. [2]
- (c) Describe **two** ways in which an online shopping site can harness the collective intelligence of its users to promote its products. [4]
- 13.** Web graphs are often used to illustrate features of the internet.
- (a) With the aid of a diagram, describe how a *bowtie structure* can be used to illustrate the principle features of a web graph. [5]
- (b) By using **one** example, explain how power laws can represent certain aspects of web development. You should use a labelled graph to illustrate your answer. [4]

End of option C

Blank page

Option D — Object-oriented programming

A small health clinic with three doctors operates in a village. All clients of the clinic have their details stored in the clinic’s database. Patients that visit the clinic during the day are given a priority rating (1–3) and are seated in a waiting room to wait for the next available doctor. When it is their turn, the patients are taken from the waiting room to have a consultation with their assigned doctor, who makes a diagnosis, provides treatment and writes a prescription.

The clinic’s system is coded in Java. There are many objects in this system and some of them are listed below.

Object	Description
Doctor	A licensed professional who treats patients in the clinic.
Patient	A sick person who requires a consultation with a doctor.
WaitingRoom	A place where patients wait for their consultations.
Consultation	A dated meeting between a doctor and a patient which results in a diagnosis, treatment and a prescription for medication.
Treatment	A dated record of all actions and medication prescribed to treat the patient’s diagnosed condition.

The three objects `Patient`, `WaitingRoom` and `Treatment` have been defined in the following UML diagrams:

```

classDiagram
    class Patient {
        Integer id
        String name
        Integer priority
        String doctor
        setId (Integer id)
        setName (String name)
        setPriority (Integer priority)
        setDoctor (String doctor)
        Integer getID()
        String getName()
        Integer getPriority()
        String getDoctor()
        String toString()
    }
    
```

```

classDiagram
    class WaitingRoom {
        Patient[10]patients
        add(Patient newPatient)
        void callNextPatient()
        Integer findNextPatientIndex()
        remove(Integer n)
    }
    
```

```

classDiagram
    class Treatment {
        String date
        Integer patientId
        String doctor
        String actions
        String medication
        setDate (String date)
        setPatientId (Integer id)
        setDoctor (String doctor)
        setActions (String actions)
        setMedication (String medication)
        String getDate()
        Integer getPatientID()
        String getDoctor()
        String getActions()
        String getMedication()
        String toString()
    }
    
```

(Option D continues on the following page)

(Option D continued)

The Patient and WaitingRoom objects are implemented as follows:

```

public class Patient
{
    private int id;
    private String name;
    private int priority;
    private String doctor;

    public Patient(int i, String n, int p)
    {
        id = i;
        name = n;
        priority = p;
        doctor = null;
    }
    public void setId(int i) { id = i; }
    public void setName(String n) { name = n; }
    public void setPriority(int p) { priority = p; }
    public void setDoctor(String d) { doctor = d; }
    public int getId() { return id; }
    public String getName() { return name; }
    public int getPriority() { return priority; }
    public String getDoctor() { return doctor; }
    public String toString() { return id+" "+name+" "+priority+" "+doctor; }
}

public class WaitingRoom
{
    private Patient[] patients = new Patients[10];

    // uses default constructor

    public void add(Patient newPatient)
    // adds the new patient in the next empty array location
    {
        int i = 0;
        while ((patients[i] != null) && (i < 10))
        {
            i=i+1;
        }
        if (i==10) { System.out.println("No more space in the waiting room."); }
        else { patients[i] = newPatient; }
    }
}

```

(Option D continues on the following page)

(Option D continued)

```
public void callNextPatient()
// finds the next patient, outputs their details
// and removes the patient from the array
{
    int index = 0;
    if (patients[0]==null)
    {
        System.out.println("The waiting room is empty.");
    }
    else
    {
        index = findNextPatientIndex();
        remove(index);
    }
}

private int findNextPatientIndex()
// returns the index of the first patient with the
// highest priority in the array patients
{
    int max = 0;
    //... code missing ...
    return max;
}

private void remove(int n)
// outputs the data of the patient instance at array index n
// and removes that patient by shifting all remaining patients
// by one index towards the front of the array
{
    //... code missing ...
}
}
```

(Option D continues on the following page)

(Option D continued)

- 14. (a) Define the term *constructor*, using an example from the code on pages 14 and 15. [2]
- (b) Describe **one** additional field that might have been included in the `Patient` class. Include a data type and sample data in your answer. [2]
- (c) Describe the relationship between the `Patient` object and the `WaitingRoom` object. [2]

Consider the `WaitingRoom` class as presented on pages 14 and 15.

- (d) Construct the missing lines of code in the `findNextPatientIndex()` method to return the index of the first patient with the highest priority in the `patients` array. **Note:** the highest possible priority is 3. [3]
 - (e) Construct the `remove(int n)` method which outputs the data of the patient object at index `n` and then removes that patient object by moving all remaining patient objects one index towards the front of the `patients` array. You may assume that `n` is a valid index between 0 and 9, and that an instance of `Patient` exists at that index. [6]
15. (a) In relation to the `Patient` class, outline **one** advantage of encapsulation. [2]
- (b) In relation to the `Treatment` object, discuss **one** ethical consideration when designing software that stores patients and their illnesses. [4]

The clinic would like to start storing details in a `Doctor` object, including full name, telephone number and whether the doctor is present or not. For example:

name:	Dr Henriëtte Mănescu-Rața
phone:	0734511122
present:	true

- (c) Design the `Doctor` object using a UML diagram. [3]
- (d) In relation to the `Doctor` object, outline the need for extended character sets as used by modern programming languages. [3]

(Option D continues on the following page)

(Option D continued)

16. `Treatment` objects are being instantiated throughout the day and added to a collection. The object `treatmentFile` contains the following methods which act on that collection:

- `getNext()` which reads the next treatment from the collection and returns it
- `hasNext()` which returns false when there are no more treatments in the collection.

Construct the method `showMedicationByDoctor()`, which will take the name of a doctor as a parameter and output the medication for each treatment in the collection that has been provided by that doctor. You may assume that `treatmentFile` has been declared as a global variable, that it is open for reading, and that the first time `getNext()` is called it will return the first treatment from the collection.

[6]

17. The `Treatment` object needs to be developed further. There are three possible types of treatment and this is to now be recorded.

- `ambulatory` – the patient is treated and goes home afterwards
- `in-patient` – the patient spends one or more nights in the clinic
- `referral` – the patient is sent to a hospital in a nearby city.

All treatments have common fields such as ID of the patient, date and a doctor object, but other fields are different. For example, `ambulatory` and `in-patient` treatments include medication while `referral` does not. On the other hand, `referral` includes the name of the hospital that the patient was sent to and whether or not ambulance transportation was used. `In-patient` treatment includes a room number.

(a) Construct diagrams to show how inheritance can be used to re-design the `Treatment` class.

[6]

(b) Describe **three** advantages of modularity in program development.

[6]

(Option D continues on the following page)

(Option D continued)

18. Due to the growth of the village, more people have been using the clinic and the current static implementation of the waiting room is no longer suitable. The waiting room needs to be implemented dynamically with a structure that preserves the order that the patients have come into the clinic.

(a) (i) State why a stack is not suitable for this purpose. [1]

(ii) Outline **one** typical application of a stack. [2]

It has been decided that a linked-list will be used to hold the individual `Patient` objects.

An object of the `LinkedList` class will be used to instantiate a dynamic list of patients to implement the `WaitingRoom` as follows.

```
public class WaitingRoom
{
    private LinkedList<Patient> PatientList = new LinkedList<Patient>();
    // methods
    public void add(Patient P)
    // adds a patient at the end of the list
    {
        PatientList.addLast(P);
    }
    public void remove()
    // outputs the name of the next patient to see a doctor and
    // removes this patient instance from the list
    {
        int index = findNextPatientIndex();
        System.out.println(PatientList.get(index).getName());
        PatientList.remove(index);
    }
    private int findNextPatientIndex()
    {
        int i = 0, result = 0;
        Patient current, firstup;
        firstup = new Patient();
        firstup.setPriority(0);
        while (i < PatientList.size())
        {
            current = PatientList.get(i);
            if (current.getPriority() > firstup.getPriority())
            {
                firstup = current;
                result = i;
            }
            i=i+1;
        }
        return result;
    }
}
```

(Option D continues on the following page)

(Option D, question 18 continued)

(b) The `remove` method could cause a run-time error. State the pre-condition for the `findNextPatientIndex` method, in order to avoid this error. [1]

(c) Consider the following list:

Copy and complete the table below to trace a call to the `findNextPatientIndex` method for this list. **Note:** the initialization is given in the first row.

<code>i</code>	<code>current.name</code>	<code>firststep.name</code>	<code>result</code>
0	-	null	0
0			

[3]

(d) State the purpose of the `findNextPatientIndex` method. [1]

(e) Outline the changes needed to improve the `findNextPatientIndex` method with an early exit from the loop. [3]

(Option D continues on the following page)

(Option D continued)

19. Consider the following fragment of code that implements the method `result()`, where `x` and `y` are non-negative numbers.

```
public int result(int x, int y)
{
    if (x==0)
    {
        return 0;
    }
    else if (y == 0)
    {
        return 1;
    }
    else
    {
        return (x+y)*result(x, y-1)
    }
}
```

- (a) Define *recursion*. [1]
- (b) Trace the method `result(3, 4)` showing the intermediate steps and the final evaluation of this call. [4]

An electronic amplifier uses a variant of `result()`, to produce distorted special effects whilst a music instrument is being played.

The method `result4()`, with the signature

```
double result4(double x, int y, double z, int v),
```

produces these special effects, taking four non-negative signals in input, and obeying the following specification:

- if the first three inputs (`x`, `y` and `z`) have a combined value that is more than 12 times the value of `v`, then the method behaves as `result(v, y)`
- otherwise, and if the value of `y` is less than half the value of `x`, the method `result4()` is called again, only now with `y` and `v` decremented by 3, unless this would make their values invalid
- if none of these actions are possible, `result4()` behaves as `result(0, 0)`.

- (c) Construct the method `result4()`, according to the given specification. [4]

End of option D
