2.1 Demand

Contents

2.1.1 Demand, Price & Quantity

Your notes

Introduction to Demand

- **Demand is the amount of a good/service that a consumer is willing and able to purchase at a given price in a given time period**
  - If a consumer is willing to purchase a good, but cannot afford to, it is not **effective demand**
- A **demand curve** is a graphical representation of the **price** and **quantity demanded (QD)** by consumers
  - If data were plotted, it would be an **actual curve.** Economists, however, use straight lines so as to make analysis easier
- **The law of demand** states that there is an inverse relationship between price and quantity demanded (QD), **ceteris paribus**
  - When the price rises the QD falls
  - When the price falls the QD rises

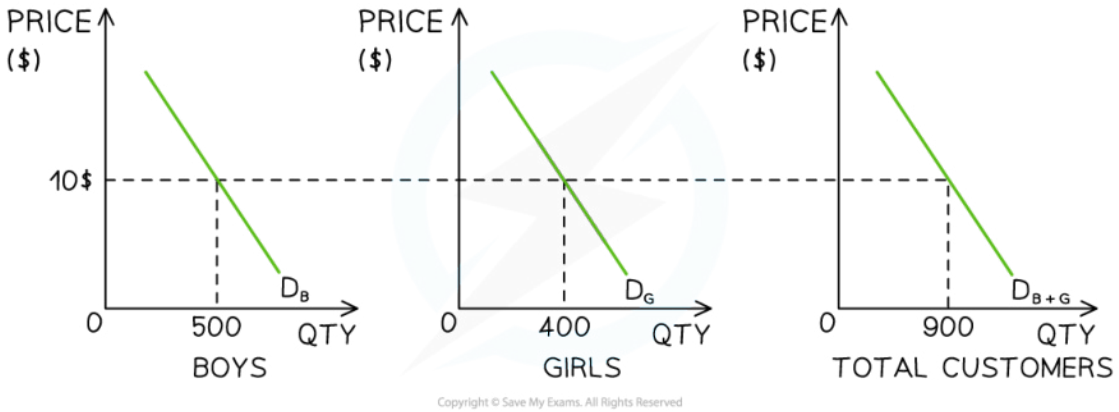
Individual and Market Demand

- **Market demand** is the combination of all the **individual demand** for a good/service
  - It is calculated by adding up the individual demand at each price level

The Monthly Market Demand for Newspapers in a Small Village

Customer 1	Customer 2	Customer 3	Customer 4	Market Demand
30	15	4	4	**53**

- **Individual and market demand** can also be represented graphically



Market demand for children's swimwear in July is the combination of boys and girls demand

Your notes

Diagram Analysis

- A shop sells both boys and girls swimwear
- In July, at a price of $10, the demand for boys swimwear is 500 units and girls is 400 units
- At a price of $10, the shops **market demand** during July is 900 units

Assumptions Underlying the Law of Demand

- The law of demand is based on **three key assumptions**:
  - The income effect
  - The substitution effect
  - The law of diminishing marginal utility
- These three assumptions collectively contribute to the understanding of the law of demand and **how consumers' behaviour is influenced by changes in price**
  - The income effect and substitution effect highlight how changes in price affect consumers' purchasing power and their choices among different goods
  - The law of diminishing marginal utility explains why consumers are **less willing to pay higher prices for additional units** of a good

An Explanation of the Three Assumptions

The Assumption	Explanation

The Income Effect	▪ The income effect refers to the change in a **consumer's purchasing power** resulting from a change in the price of a good/service
	  ▪ When the price of a good decreases, **consumers' purchasing power increases** as **with the same income** they can buy more of the good
	  ▪ When the price of a good increases, **consumers' purchasing power decreases** as **with the same income** they can afford to purchase less of the good
	▪ The income effect **assumes** that consumers will **adjust their consumption patterns** based on changes in their purchasing power caused by price fluctuations

The Substitution Effect	▪ The substitution effect suggests that **consumers will substitute goods/services** that have become **relatively more expensive** with those that have become relatively less expensive
	  ▪ When the price of a particular good rises, consumers may seek alternatives that provide similar utility or satisfaction at a lower cost
	  ▪ E.g. if the price of brand A coffee increases, consumers may switch to brand B coffee, assuming it provides a similar level of satisfaction but at a lower price
	▪ The substitution effect assumes that consumers are **rational decision-makers** who have perfect information and respond to changes in relative prices by adjusting their consumption

The Law of Diminishing Marginal Utility	▪ **The Law of Diminishing Marginal Utility** states that as additional products are consumed, the utility gained from t**he next unit** is lower than the utility gained from the **previous unit** ▪ **Marginal utility** is the additional utility **(satisfaction)** gained from the consumption of **an additional product** ▪ The utility gained from consuming the first unit is usually **higher** than the utility gained from **consuming the next unit** ▪ For example, a hungry consumer gains **high utility** from eating their **first hamburger**. They are still hungry and purchase a **second hamburger** but gain **less satisfaction** from eating it than they did from the first hamburger

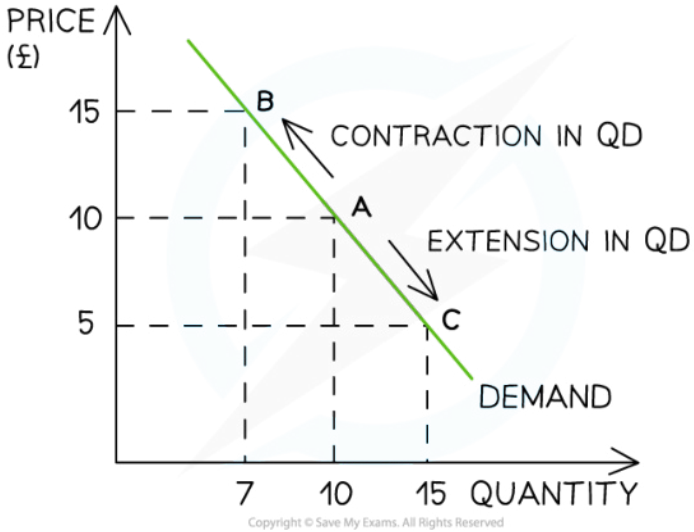
Your notes

	▪ **Lowering the price** makes it a more attractive proposition for the consumer to **keep consuming** additional units - and there is a **movement down the demand curve**

Your notes

Movements Along a Demand Curve

- If **price** is the only factor that changes (**ceteris paribus**), there will be a change in the quantity demanded **(QD)**
  - This change is shown by a **movement along the demand curve**



A demand curve showing a contraction in quantity demanded (QD) as prices increase and an extension in quantity demanded (QD) as prices decrease

Diagram Analysis

- An **increase** in price from £10 to £15 leads to a movement **up** the demand curve from point A to B
  - Due to the **increase** in price, the QD has **fallen** from 10 to 7 units
  - This movement is called a **contraction** in QD
- A **decrease** in price from £10 to £5 leads to a movement **down** the demand curve from point A to point C
  - Due to the **decrease** in price, the QD has **increased** from 10 to 15 units

- This movement is called an **extension** in QD

Your notes

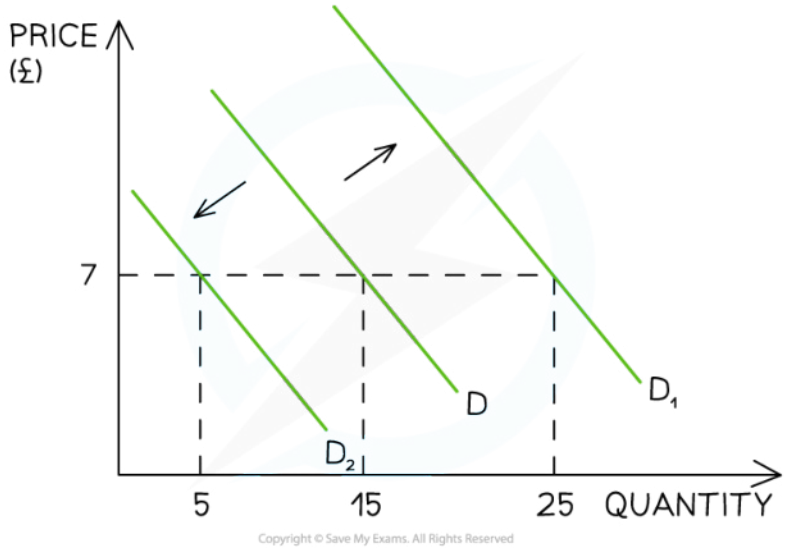
2.1.2 Non-Price Determinants of Demand

Your notes

Shifts of the Demand Curve

- There are numerous factors that will **change the demand** for a good/service, **irrespective of the price level**. Collectively these factors are called the **non-price determinants of demand** and include
  - Changes in real income
  - Changes in tastes/preferences
  - Changes in the price of related goods (substitutes and complements)
  - Changes in the number of consumers
  - Future price expectations

- Changes to each of the non-price determinants, **shifts the entire demand curve** (as opposed to a movement along the demand curve)



A graph that shows how changes to any of the non-price determinants shifts the entire demand curve left or right, irrespective of the price level

- For example, if a firm **increases** their **Instagram advertising**, there will be an **increase in demand** as more consumers become aware of the product
    - This is a **shift in demand** from D to D_1. The price remains unchanged at £7 but the **demand has increased** from 15 to 25 units

Your notes

An Explanation of how each of the Non-Price Determinants of Demand Shifts the Entire Demand Curve at Every Price Level

Non-Price Determinant	Explanation	Condition	Shift	Condition	Shift
Changes in real income	▪ **Real Income** determines how many goods/services can be enjoyed by consumers ▪ There is a **direct** relationship between income and demand for **goods/services**	**Income Increases**	**D Increases Shifts Right ($D \rightarrow D_1$)**	**Income Decreases**	**D Decreases Shifts Left ($D \rightarrow D_2$)**
Changes in taste/preferences	▪ If goods/services become more **preferable** then **demand** for them increases ▪ There is a **direct relationship** between changes in **taste/preferences** and **demand** ▪ **Advertising or branding** can change tastes/preferences	**Good becomes more preferable**	**D Increases Shifts Right ($D \rightarrow D_1$)**	**Good becomes less preferable**	**D Decreases Shifts Left ($D \rightarrow D_2$)**

Changes in the prices of substitute goods **(Related goods)**	▪ Changes in the price of **substitute goods** will influence the demand for a product/service ▪ There is a **direct relationship** between the **price of good A** and **demand for good B** ▪ E.g. The price of a Sony 60" TV (good A) increases so the **demand** for LG 60" TV (good B) increases	**Price of Good A Increases**	**D for Good B Increases Shifts Right ($D \rightarrow D_1$)**	**Price of Good A Decreases**	**D for Good B Decreases Shifts Left ($D \rightarrow D_2$)**
Changes in the prices of complementary goods **(Related goods)**	▪ Changes in the price of **complementary goods** will influence the demand for a product/service ▪ There is an **inverse relationship** between the **price of good A** and **demand for good B** ▪ For example, the price of printer ink (good A) increases so the **demand** for ink printers (good B) decreases	**Price of Good A Increases**	**D for Good B Decreases Shifts Left ($D \rightarrow D_2$)**	**Price of Good A Decreases**	**D for Good B Increases Shifts Right ($D \rightarrow D_1$)**
Changes in the number of consumers	▪ If the **population size** of a country changes over time, then the **demand** for goods/services will also change ▪ There is a **direct relationship** between the changes in	**Population Increases**	**D Increases Shifts Right ($D \rightarrow D_1$)**	**Population Decreases**	**D Decreases Shifts Left ($D \rightarrow D_2$)**

Your notes

Your notes

	population size and demand ▪ Demand will also change if there is a change to the **age distribution** in a country as different ages **demand different goods/services** e.g an ageing population will buy more hearing aids				
Future price expectations	▪ If consumers **expects the price** of a good/service to **increase** in the future, they will purchase it now and demand will increase ▪ If consumers **expects the price** of a good/service to **decrease** in the future, they will wait to purchase it later and demand will decrease	**Expectations price will rise**	**D Increases Shifts Right ($D \rightarrow D_1$)**	**Expectations price will fall**	**D Decreases Shifts Left ($D \rightarrow D_2$)**

EXAMINER TIP

The difference between a **movement along the demand curve** and a **shift in demand** is essential to understand. You will be repeatedly examined on this and it is important that you use the **correct language** to show that you understand the difference between **a change in quantity demanded** and a **change in demand.**

When **price changes** (ceteris paribus), there is a movement along the demand curve resulting in a change to **quantity demanded**. When a **non-price determinant of demand changes,** there is a shift of the entire demand curve resulting in a **change to demand.**
